CHAPTER I

INTRODUCTION

The success of a construction project from the point of view of the contractor can be defined in different terms. However, of all possible definitions the most important may be the profit generated by a single project. In cases where the project management concept is used, the construction manager is tasked with the overall management of design, procurement, construction operations. In these types of projects, the construction manager also has the greatest amount of influence in controlling costs and generating profit. However, in the case of competitively advertised, fixed-price government construction contracts, the extent of contractor influence is normally limited to the procurement/construction portion of the project's life cycle. Therefore, the contractor's degree of success is highly dependent on two different operations that occur during procurement and construction phases of the project. The first operation, project planning, involves estimating the labor, materials, equipment, and preliminary schedule needed to execute a project as established by the owner's design. The second operation, the implementation phase, is for the most part dependent on the prior planning. In the case of a fixed-price contract, the project cost as

presented in the base bid also becomes the control amount upon which the contractor's control budget is based. Therefore, what estimating and planning is done in the preparation of the base bid can be considered essential to the success of the construction project.

However, there is a certain amount of uncertainty in the bidding process. Material quotes may be based on materials that do not conform to the specifications. The material take-off may contain errors that result in quantities different than what is required. Equipment costs are based on what the estimator considers to be the most efficient piece of equipment for the job while not knowing what will be available at the time the equipment is needed.

Overall, the items noted above can be considered to be controllable and therefore not subject to creating substantial additive costs. In comparison, however, estimating labor productivity is the most complicated part of the estimating process. Many of the factors influencing labor productivity are highly qualitative in nature, and a great deal of experience and judgement is needed to develop the type of qualitative information that is required. However, the productivity component also offers the contractor by far the greatest opportunity to control his labor costs, assuming that the contractor also has some basic understanding of the factors that influence the variable in this equation.

Preliminary estimates of productivity are normally based on either average or historical productivity rates. However, average productivity rates normally do not consider climatic effects. Historical productivity rates consider climatic effects only if prior construction projects have been executed in similar conditions. Therefore, for the estimator that is basing productivity solely on average productivity or dissimilar historical rates, there is a high probability that adverse climatic conditions will result in unforeseen additive costs that only serve to deduct from the desired profit.

The ability to anticipate adverse climatic conditions also has legal implications. As noted above, a schedule that does not address or take into account climatic conditions will more than likely be subject to delay. However, precedence has been set that daily variations in weather patterns should be expected. Precedence goes on to state that climatic conditions are only to be considered adverse when a condition arises and that condition is considered to be occurring at an unusual time of the year. Therefore if the climatic condition is not unusual for the particular time and place, or if a contractor should have reasonably anticipated it, the contractor would not be entitled to relief [1].

Therefore, the question that arises is how does a contractor estimate productivity for a project subjected to adverse climatic conditions and how do these efficiencies

impact on schedule and cost estimates. Additionally, what alternatives are available to the contractor in completing a project subject to adverse climatic conditions.

It is therefore the intent of this report to demonstrate one method of estimating productivity efficiencies and to demonstrate their impact on construction scheduling and cost. Additionally, it is intended to investigate alternatives available to the contractor.

In order to demonstrate the impact of adverse climatic conditions on project schedule and cost, an actual construction contract was selected as the basis for comparison. The project selected is a two story building of approximately 4800 square feet for fire station use including an apparatus room, a dormitory area, a living/dining area, alarm room, reception room, and administrative spaces. This facility is located at the Marine Corps Mountain Warfare Training Center (MWTC), Bridgeport, California. Construction was started in September 1984 and was completed in December 1985. Further information concerning the project and details concerning the construction execution are found in Appendix A (Page 37).

CHAPTER II

CALCULATION OF PRODUCTIVITY EFFICIENCIES FOR THE EXAMPLE PROJECT SITE

All types of productivity are influenced by air temperature, wind velocity, relative humidity, precipitation, and light. Therefore, it is universally accepted that operations in adverse climatic conditions suffer from a loss of productivity - the extent of which depends upon, in part, the type of activity and the degree of protection.

Adverse conditions, here limited to both warm and cold conditions, create varying degrees of problems. In general, the effect of adverse climatic conditions on construction projects plays a major part on the success of the project. Adverse conditions have been shown to require considerable planning due to the impact on [2]:

- 1) Arrival of personnel
- 2) Transportation of equipment
- 3) Delivery of materials
- 4) Construction of temporary shelters
- 5) Environmental protection

However, not only does severe conditions effect different facets of a construction project, but it also can have a severe impact on individuals. In extreme conditions,

studies have indicated that workers would more likely be subject to the following factors [3,4]:

- 1) Errors in judgement
- 2) Carelessness
- 3) Complaints
- 4) General lethargy
- 5) Irritability and poor mental attitudes
- 6) Decrease in quality of workmanship
- 7) General slowdown of work pace
- 8) Unscheduled stoppage of work

In warm climates, injuries take the form of sunburn, cramps, heat exhaustion and heat stroke. These types of injuries can be prevented by utilizing preventive measures such as ensuring adequate salt and water intake, proper work/rest cycles and adequate acclimatization. These preventive measures, however, generally result in an overall slowdown and, therefore, reduced productivity.

In comparison, cold weather brings about a wider range and a more severe degree of injury. Wind chill guidelines indicate that in an equivalent temperature of -25°F (which can occur with an actual thermometer temperature of 10°F combined with a 20 mile per hour wind) exposed dry skin may freeze within one minute. It has also been shown that frostbite can occur in relatively warm temperatures (30°F) if the skin is wet and the wind speed is 15 miles per hour.

Prevention of cold weather injuries is complicated in a construction environment. Normally, proper clothing is

required for exposed workers with the materials being light-weight and designed with a great degree of mobility. However, protective clothing creates the problem of maintaining a worker's skin dry. This results in a decrease in the body's pain threshold of approximately 5°F and the risk of frostbite is greatly increased.

In order to reduce the effect of cold weather, temporary shelters are often built [5]. However, these temporary shelters result in increased field overhead costs attributable to the cost of the shelter itself, the cost of heating the shelter, and the cost of maintaining the shelter.

Therefore, it can be inferred that a cold weather environment will have a greater impact on productivity, schedule, and costs. The problem, therefore is to estimate productivity rates, establish a construction schedule, and determine costs based on anticipated climatic conditions.

In order to do this, the contractor must do the following:

- 1) Estimate efficiencies that are based on climatic conditions.
- 2) Establish a construction schedule based on average production rates.
- 3) Apply calculated efficiencies to the average construction schedule and calculate a new schedule based on climatic conditions.

- 4) Reevaluate field overhead requirements based on a new schedule (i.e., determine requirements for temporary shelters and heating equipment in cold weather)

The first step involves the contractor utilizing the basic methodology in creating a construction schedule. As seen in the third step, the efficiencies are then applied to the average productivity rates, thereby modifying the individual activity durations and the overall schedule. The difficulty, however, is utilizing a valid and repeatable method to calculate efficiencies in a cold weather climate.

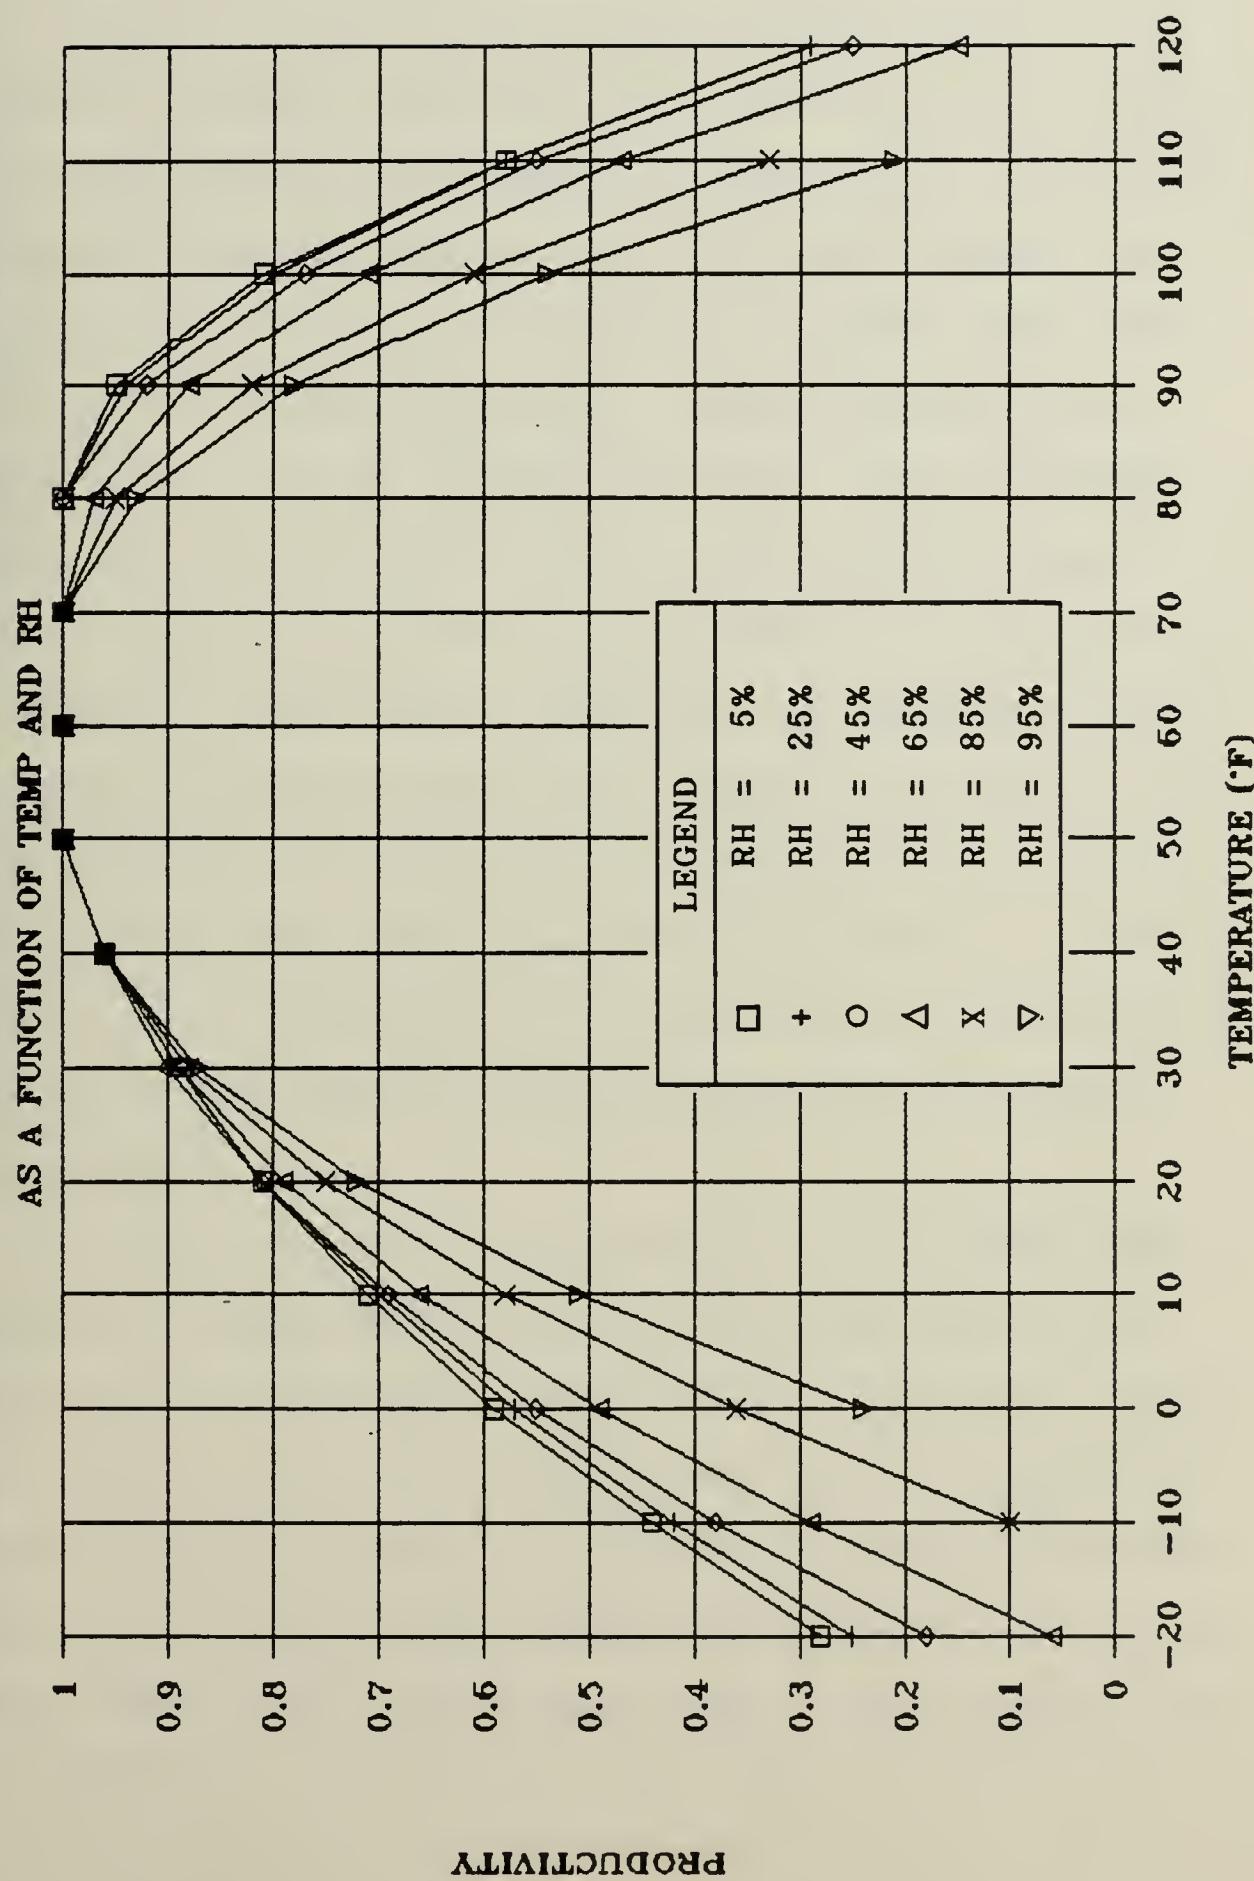

As illustrated in Appendix D (Page 65), E. Koehn and G. Brown provide one method to calculate productivity efficiencies whereby they derived two non-linear relationships for both cold and warm weather climates [6]. For the purpose of this paper, these relationships will be utilized to determine the impact of adverse climatic conditions on project schedule and cost. The expected productivity efficiency values as determined by these authors follows as Table 2-1. These productivity values are also graphically illustrated in Figure 2-1. It should be noted that these values represent efficiencies for a broad range of temperatures and humidities. For the example project, productivity efficiency values were calculated for specific site conditions. These values are shown in Table 2-3.

TABLE 2-1. CONSTRUCTION PRODUCTIVITY EFFICIENCIES AS A FUNCTION OF TEMPERATURE AND RELATIVE HUMIDITY

FIGURE 2-1. CONSTRUCTION PRODUCTIVITY AS A FUNCTION OF TEMP AND RH

As noted above, the first step is to estimate efficiencies based on historical weather data. In doing so, one must decide what data will be used and how to use it. Generally, average temperature and humidity data is easily obtainable from various sources. However, as in the case of weather data obtained from the National Oceanic and Atmospheric Administration, National Climatic Data Center (NCDC) for the example project, weather data may not be representative of the project location. For the purpose of data collection, the NCDC utilizes only specific population centers, usually supported by an airport. In the case of the example project and as indicated in Appendix A (Page 37), major population areas were twenty-five miles to the south (Bridgeport, California) and seventy miles to the north (South Lake Tahoe, California) of the site. Therefore, it may be necessary to calculate the average monthly temperature and relative humidity prior to calculating efficiencies.

For the purpose of this report, it is assumed that available average temperature and humidity data is not available for the example project site. Therefore, procedures used to calculate the required data are presented. For the purpose of these calculations, available temperature data was taken from Bridgeport, California as weather systems affect both the example project site and the town simultaneously. Humidity data was taken from South Lake

Tahoe records. Elevations of both data sources are within 1000 feet of the example project site.

In order to firmly establish seasonal trends, temperature and humidity data for a twenty year period was obtained. This provided five hundred sixty (560) to six hundred twenty (620) daily mean temperature data points for any given month from which a statistical analysis could be made.

Prior to utilizing the productivity relationships established by Koehn and Brown, a determination had to be made as to what was to be considered a proper average or typical temperature. Ultimately, it was the goal of this analysis to establish an average monthly temperature for each respective month from which productivity estimates could be made. However, with daily minimum, mean, and maximum temperatures available, a determination had to be made as to whether forecasts were based on absolute, mean, or statistically derived temperatures.

Invariably, the data can first be considered a seasonal variation in that there is a more or less regular movement within the year which occurs year after year. Therefore, in a time series with seasonal variation each month has a typical or average value position in relation to the year as a whole. The problem of seasonal variation therefore is to determine this typical or average position of each month.

Of the various methods used for measuring the seasonal variation occurring within a time series, the Simple Average Method (SAM) was selected to analyze the available temperature data [7]. Typically, SAM analyzes monthly values to establish a typical value for each of the twelve months. However, with approximately 22,000 minimum and maximum daily temperatures, the method was modified to first establish a typical value for each day of the month. The typical daily values were then used to establish a typical value for each of the twelve months. The resulting monthly values are shown in Table 2-2 below. A detailed description of the procedures used involving SAM and the analysis of the available temperature data is provided as Appendix E (Page 67).

TABLE 2-2. CALCULATED AVERAGE MONTHLY TEMPERATURES FOR MWTC BRIDGEPORT USING THE SIMPLE AVERAGE METHOD

MONTH	AVERAGE MONTHLY TEMPERATURE (°F)
JANUARY	24.95 ± 2.59
FEBRUARY	27.94 ± 1.47
MARCH	33.28 ± 1.41
APRIL	38.47 ± 1.29
MAY	47.40 ± 0.91
JUNE	55.18 ± 0.71
JULY	60.99 ± 0.67
AUGUST	59.57 ± 0.66
SEPTEMBER	52.90 ± 0.98
OCTOBER	43.43 ± 1.18
NOVEMBER	34.85 ± 1.43
DECEMBER	27.20 ± 1.30

With average monthly temperature data calculated, average productivity efficiencies for each month could be calculated using the Koehn/Brown relationships. Results of these calculations are shown in Table 2-3 below.

TABLE 2-3. CALCULATED PRODUCTIVITY EFFICIENCIES FOR MWTC BRIDGEPORT USING KOEHN/BROWN RELATIONSHIPS

MONTH	AVG MEAN TEMPERATURE (°F)	RELATIVE HUMIDITY (%)	CALCULATED PRODUCTIVITY EFFICIENCY
JANUARY	25	74	0.84

DECEMBER	26	67	0.85

CHAPTER III

ESTIMATING PROJECT SCHEDULE AND COST BASED ON CLIMATIC CONDITIONS

In order to evaluate the impact of climatic conditions on a construction project's schedule and cost, it was decided to establish five scenarios in which both schedule and cost could be traced. Prior to developing these scenarios, it was necessary to duplicate the contractor's CPM schedule in a form that could be easily cost loaded and modified. In order to accomplish this, the CPM network was duplicated on a Lotus 1-2-3 spreadsheet. Use of Lotus 1-2-3 in the construction of this CPM network and a listing of all cell formula is included as Appendix B (Page 44).

Two separate formats were used to provide for scheduling and cost loading. The first format, as seen in Appendix C (Page 53), Tables C-1 through C-5, utilizes a precedence network format to calculate early start, late start, early finish, late finish, float, and determine whether the activity is on the critical path. The second format, not shown in this report, utilized early start-early finish information to construct a Gantt chart upon which daily cost information for each activity was loaded. This cost loading information was then used to construct cost forecasts.

Scenario A was based on the actual CPM schedule used by the contractor. For this scenario, a total of 466 calendar days was used to accomplish the project. From the contractor's schedule of prices, the cost of the project to the government was \$663,810. Of the total project cost, total direct labor and material costs equalled \$520,406, including \$2,125 for maintenance during winter shutdown. Field overhead costs equalled \$117,384 or \$253.53 per calendar day. These field overhead costs included superintendent and quality control personnel wages, job trailer costs, utilities, laboratory services, etc. The remaining amount, \$26,020 is attributed to a profit of approximately 5%. The productivity efficiencies in this actual case are assumed to be at 100% and therefore not affected by climatic conditions.

Scenario B (Table C-2, Page 57), is based on the ideal case of the actual CPM without any time taken for winter shutdown. Without this time period, total project time is reduced to 289 calendar days. In comparison, total direct costs were calculated at \$518,281 and total field overhead at \$73,017. Based on the actual cost to the government (the base bid), this would have left a total of \$72,512 or 12.26% attributable to profit. It should be noted however that it is considered unreasonable to assume that construction execution will reach ideal conditions. Therefore, Scenario B shall only be used as the basic schedule from

which Scenarios C,D, & E are constructed. Scenario B, therefore, shall not be considered in any further comparative analyses.

As it is being hypothesized that temperatures affect the productivity and therefore scheduling and cost, the ideal case was then used as the basis for calculating the contract duration after applying the calculated productivity efficiencies. In order to allow for a comparison between different climate scenarios, it was decided to first use the mean temperature data to modify the project schedule. It was then decided to create worst and best case scenarios by arbitrarily subtracting from and adding to the monthly mean temperatures.

Scenario C, the precedence network based on mean climatic conditions, was created by using the calculated productivity efficiencies indicated in Table 2-3 (Page 14) to modify the ideal case in Scenario B.

For Scenario D, the average monthly temperature minus ten degrees was used. For Scenario E, the average monthly temperature plus ten degrees was used. In both scenarios, the resulting efficiencies were then factored into the resulting CPM schedule.

Table 3-1 (Page 20) shows the monthly temperatures and efficiencies used for Scenarios C, D, and E.

Once productivity efficiencies were established for the MWTC construction site, they were then factored into the cost loaded Gantt chart. Simply, the procedure utilized

was to take the monthly efficiency corresponding with the starting date of the activity and dividing the activity duration by the efficiency. This would result in a modified, usually longer, activity duration. For those activities that extended over multiple months, the efficiency used corresponded with the longest partial duration. Going through each activity of the network resulted in a listing of modified activity durations. This was then used to calculate total direct cost per activity day. These direct costs were then inserted into the cost loaded Gantt chart. The cost loaded Gantt chart was then set up to calculate total direct costs per day and cumulative direct cost per day.

The modified activity durations were then inserted into the precedence network spreadsheet to determine float and critical activities. This also served the purpose of verifying the early starts and finishes of each activity and the overall project duration.

As seen in Table C-3 (Page 59), Scenario C, based on mean climatic conditions, resulted in a total project duration of 306 calendar days. Total direct costs again were calculated at \$518,281. Field overhead was calculated at \$77,327. Based on the actual cost to the government (\$663,810), a total of \$68,202 is left for potential profit.

As seen in Table C-4 (Page 61), Scenario D, based on temperatures ten degrees below the calculated monthly mean

temperatures, resulted in a total project duration of 327 calendar days. Total direct costs were verified at \$518,281. Field overhead costs were calculated at \$82,651. Based on the actual cost to the government, a total of \$62,878 is left for potential profit.

As seen in Table C-5 (Page 63), Scenario E, based on temperatures ten degrees above the calculated monthly mean temperatures, resulted in a total project duration of 296 calendar days. Total direct costs were verified at \$518,281. Field overhead costs were calculated at \$74,284. Based on the actual cost to the government, a total of \$71,245 is left for potential profit.

The costs noted above for Scenarios C through E, however, are misleading. In the actual execution of the example project, the contractor shut down the job from the beginning of October through to the beginning of April. A review of the activities surrounding this shutdown also indicates that the work done immediately before and after the shutdown did not require any extraordinary measures to protect work or construction personnel. In the actual schedule, the first activity that occurred that would require monitoring of weather conditions (concrete placement) didn't occur until June. In addition, the exterior finishes that were also temperature dependent (the exterior insulation finish system (EIFS) and the roof membrane) were completed prior to the onset of winter. Therefore, all

TABLE 3-1. MONTHLY TEMPERATURES AND CALCULATED
EFFICIENCIES FOR SCENARIOS C, D, & E

Month	Temperature (Efficiency)		
	Scenario C (Mean Temp)	Scenario D (Mean Temp - 10 °F)	Scenario E (Mean Temp + 10 °F)
January	25 (0.84)	15 (0.71)	35 (0.93)
February	28 (0.87)	18 (0.75)	38 (0.95)
March	33 (0.92)	23 (0.83)	43 (0.98)
April	38 (0.95)	28 (0.88)	48 (0.99)
May	47 (0.99)	37 (0.95)	57 (1.00)
June	55 (1.00)	45 (0.98)	65 (1.00)
July	61 (1.00)	51 (1.00)	71 (1.00)
August	59 (1.00)	49 (1.00)	69 (1.00)
September	52 (1.00)	42 (0.97)	62 (1.00)
October	43 (0.98)	33 (0.92)	53 (1.00)
November	34 (0.93)	24 (0.84)	44 (0.98)
December	26 (0.85)	16 (0.74)	36 (0.94)

work that was temperature dependent was done at a time where little or no protection was required.

Scenarios C, D, & E, however, force temperature dependent activities into the winter thereby requiring some level of protection. The cost of this protection, then, will offset the potential profit.

For the purpose of this report, arbitrary decisions are made concerning weather protection. A review of contract specifications indicates the following areas as temperature dependent:

- 1) Section 03301, Cast-in-place Concrete
- 2) Section 04230, Reinforced Masonry
- 3) Section 07111, Elastomeric Waterproofing,
Sheet Applied
- 4) Section 07240, Exterior Insulation Finish System
- 5) Section 07920, Sealants and Caulking
- 6) Section 09310, Ceramic Tile
- 7) Section 09650, Resilient Tile
- 8) Section 09910, Painting of Buildings

Scenarios C, D, and E were then evaluated to establish weather protection requirements.

It was first assumed that the target period for weather protection would be from the beginning of October through to the beginning of April, matching the winter shutdown period in the actual contract. From within that period, each scenario was reviewed to identify where in the schedule the first temperature dependent activity occurred.

Then, each scenario was reviewed to establish the end of the last temperature dependent activity within the protection period. This period was then noted as the duration in which some sort of weather protection and supplemental heating would be required.

After initial review of the three scenarios, it was decided that it would be assumed that one enclosure could be constructed to protect the construction area. It was therefore assumed that the enclosure would allow for ten feet of clear space around the building and for a fifteen foot clearance above the structures highest elevation. This then required an enclosure of 77 feet wide by 87 feet long by 52 feet high for a total of 348,348 cubic feet of enclosed and heated space. For the purpose of this report, it was assumed that the enclosure would be constructed of heavy duty steel tubular scaffolding along the perimeter covered with a reinforced, oil resistant, fire retardant, polyethylene tarpaulin. It was also assumed that both the scaffolding and the tarpaulin were rented. Due to the nature of the enclosure, it was also assumed that fourteen calendar days would be required to both set up and remove the enclosure. From current pricing data, it was estimated that both set up and removal would cost a total of \$5,000 each time and that rental would cost \$6,020 per month.

Taking set up, protection and removal periods into consideration, Table 3-2 (Page 23) indicates the time periods for weather protection for the three scenarios. Calcu

TABLE 3-2. CRITICAL DATES FOR TEMPORARY
SHELTERS FOR SCENARIOS C, D, & E

Activity Description	Scenario		
	C	D	E
Start construction of shelter	14 NOV 84	20 NOV 84	30 NOV 84
Complete construction of shelter, start heating	28 NOV 84	4 DEC 84	14 DEC 84
Complete heating, start demolition of shelter	15 MAR 85	3 APR 85	2 APR 85
Complete demolition of shelter	29 MAR 85	17 APR 85	15 APR 85

lations for estimated fuel costs and heater rental also are to be included in the estimates for winter protection. These costs are summarized below. Assumptions and calculations concerning these costs are found in Appendix F (Page 108).

Based on these heating scenarios, potential profit for Scenario C is affected as follows:

Set up of shelter:	\$5,000
Shelter rental:	\$21,177
Shelter removal:	\$5,000
Heater rental:	\$5,113
Heater fuel:	\$12,060
 Total Cost for Protection:	 \$48,350
 Potential Profit:	 \$68,202
 Anticipated Profit after subtracting protection costs	 \$19,852

Based on these heating scenarios, potential profit for Scenario D is affected as follows:

Set up of shelter:	\$5,000
Shelter rental:	\$23,750
Shelter removal:	\$5,000
Heater rental:	\$5,728
Heater fuel:	\$14,236
 Total Cost for Protection:	 \$53,714
 Potential Profit:	 \$62,878
 Anticipated Profit after subtracting protection costs	 \$9,164

Based on these heating scenarios, potential profit for Scenario E is affected as follows:

Set up of shelter:	\$5,000
Shelter rental:	\$21,573
Shelter removal:	\$5,000
Heater rental:	\$5,160
Heater fuel:	\$11,449

Total Cost for Protection:	\$48,182
Potential Profit:	\$71,245
Anticipated Profit after subtracting protection costs	\$23,063

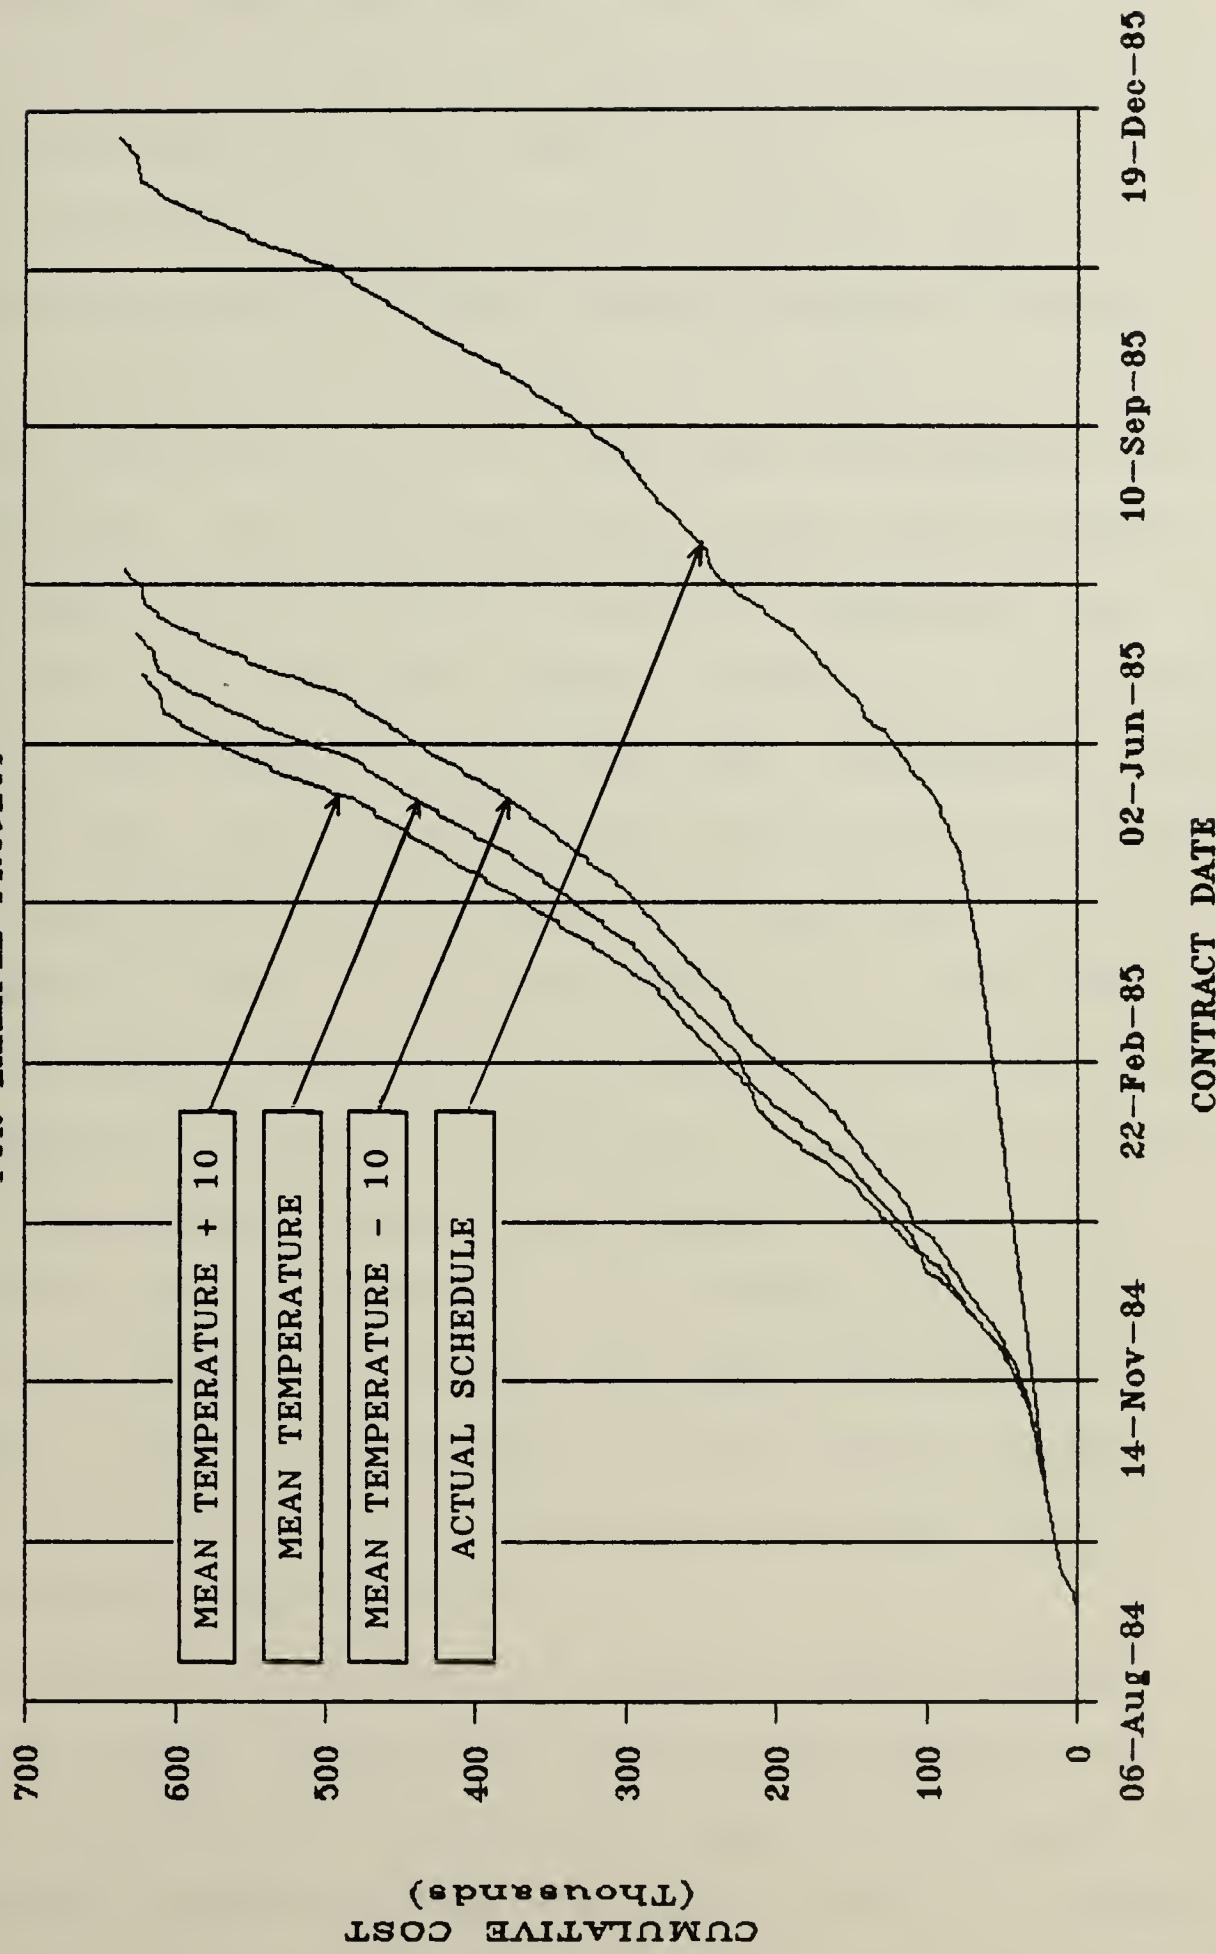

The impact of the winter protection costs on the overall cumulative costs is graphically shown on the cost forecasts in Figure 3-1.

The following is a summary of all factors used to compare Scenario A, the actual project, to Scenarios C, D, and E.

In terms of critical activities, Table C-1 (Page 55) identifies a total of twenty five activities deemed critical. Review of Scenarios C, D, and E and the application of the productivity efficiencies to the 69 activities indicate that the activities originally deemed critical remain critical after the application of the efficiencies. This then serves to validate the method in which the efficiencies were factored.

In addition, the application of productivity efficiencies had little impact on the available float. Overall, the efficiencies applied had little effect on the duration of the individual activities. Scenario C, with a mean efficiency of 0.94, only resulted in a seventeen (17) calendar day increase in the overall schedule. This would leave little time available to add to the float of all the non-critical activities. Even in the worst case, Scenario D where temperatures ten degrees below the mean were consid

FIGURE 3-1. COMPARATIVE COST FORECAST
FOR EXAMPLE PROJECT

ered, the mean efficiency stands at 0.88. This results in increases in float above 30% in only three of the 44 non-critical activities. All remaining non-critical activities gain one or two days in float.

In the case of overall project duration, there is a definite advantage to working during periods of adverse climatic conditions. Scenarios A, C, D, and E have overall project durations of 466, 306, 327, and 296 calendar days, respectively. The first advantage is that the contractor can reduce direct costs by eliminating a caretaker force during the winter shutdown period. Though, for the example project, this equates to only less than one percent of the direct costs, this could increase substantially for other projects depending on the severity of the weather and on the amount of the work in place that must be maintained.

The primary advantage to a shorter project duration is the reduction in field overhead costs. As indicated previously, the example project was estimated to incur field overhead costs of \$117,384. Field overhead costs for Scenarios C, D, and E, in comparison ranged from \$74,284 to \$82,651. This alone represents a 29-36 percent decrease in costs. For a fixed-price construction project, this savings becomes potential profit.

However, as indicated previously, working through adverse climatic conditions does come without additive costs. In Scenario A, the actual construction project, the contractor's period of winter shutdown resulted in minimal

costs (\$2,125) due to caretaker maintenance. In Scenarios C, D, and E, the cost for a temporary shelter and supplemental heating would have cost the contractor an average of \$50,082. This cost would then have an impact on the potential profit.

In terms of the potential profit, Scenario A estimates a profit of \$26,020, or 5.0% of the direct costs. In comparison, Scenario C estimates an anticipated profit of \$19,852 after deducting the cost of weather protection. This anticipated profit represents only 3.8% of the direct costs, a decrease from the actual 5%. Scenario D estimates an anticipated profit of \$9,164, only 1.7% of the estimated direct costs. Lastly, Scenario E estimates an anticipated profit of \$23,063, or 4.4% of the estimated direct costs. It should be noted, however, that for the purposes of estimating project costs, only those values generated by Scenario C would be considered. A review of the estimated temperatures for the three scenarios indicates that the temperatures used in Scenarios D and E are well outside of the range of values generated for Scenario C. A cursory review of this data would indicate that there is little probability that the daily mean temperatures would continuously be outside of the range of the calculated mean value. If mean temperature values were to continuously remain outside of the expected range, the contractor would then have reason to claim unusual adverse conditions thereby setting the stage for damages.

In order to test the validity of the procedures, a sensitivity analysis was conducted by, first, varying the expected mean temperature during the winter protection period and evaluating the resulting anticipated profit, and secondly, by varying the length of the winter protection period and evaluating the resulting profit. In both cases, Scenario C, the mean temperature case was used.

In the case of varying the expected mean temperature during the winter protection period, it was anticipated an increase in the mean temperature would reduce the requirement for heating and therefore reduce winter protection costs and increase profit. Temperatures for the months November through March were increased incrementally using the average standard error for the months in question. The resulting winter protection costs, profit, and mean temperature for the winter protection period were then calculated. Results are shown below in Table 3-3.

TABLE 3-3. EXPECTED WINTER PROTECTION COSTS AND PROFIT AS A FUNCTION OF MEAN DAILY TEMPERATURE.

AMOUNT OF INCREASE (°F)	EXPECTED PROTECTION COSTS	EXPECTED PROFIT	RESULTANT MEAN TEMPERATURE (°F)
0.00	\$48,344	\$19,858	29
1.64	\$48,227	\$19,974	31
3.28	\$48,111	\$20,091	33
4.92	\$47,994	\$20,207	34
6.56	\$47,878	\$20,324	36
9.84	\$47,644	\$20,557	39
10.50	\$47,598	\$20,604	40

The significance of Table 3-3 above is that as hypothesized, an increase in the average mean temperature during the winter protection period will decrease the winter protection costs and therefore increase the profit. However, of particular note is that once the average mean temperature is above 40°F, there is no longer a requirement for winter protection. Therefore, winter protection costs would equal zero. However, once the mean temperature for the winter protection period goes below 40°F, the contractor can plan on spending a minimum of \$47,598. This cost would include set up, rental of both shelter and heaters, dismantling the shelter and minimal fuel costs. At no time is this analysis, does the expected profit match or exceed that of the actual case. Of major significance is that a major increase in average mean temperature will produce little in the way of savings.

Of equal significance is the probability of the average mean temperature increase to a degree in which winter protection costs can be disregarded. It should be pointed out that an increase in mean daily temperatures for the entire winter protection period are unrealistic just by the nature of the available temperature data.

Sensitivity analysis was also conducted on the length of the winter protection period. In doing this analysis, it is anticipated that a decrease in the length of the winter protection period will also decrease the overall winter protection costs and increase expected profit. In

Scenario C, heating and a temporary shelter was provided from 28 November to 15 March, a total of 107 calendar days. Two additional data points were then calculated for winter protection periods ending 28 February and 31 March. Results of this analysis are found below in Table 3-4.

TABLE 3-4. EXPECTED WINTER PROTECTION COSTS AND PROFIT AS A FUNCTION OF DURATION OF WINTER PROTECTION

LENGTH OF WINTER PROTECTION (CD)	EXPECTED PROTECTION COSTS	EXPECTED PROFIT
93	\$43,381	\$24,821
107	\$48,350	\$19,852
124	\$54,383	\$13,819

As hypothesized, the shorter the winter protection period, the lower the winter protection costs. Of significance is that the decrease in the winter protection duration brings about a greater degree in reduced costs than increased mean daily temperatures. However, as indicated in the previous sensitivity analysis, one reason for decreasing the winter protection period may be the arrival of warmer weather. This would mean that the mean daily temperatures would require to be above 40°F for a period of over 30 days before anticipated increase in order to match the anticipated profit identified in Scenario A. Basing increased savings solely on anticipated temperatures decreasing the length of the winter protection period may be totally unreasonable and expose the contractor to undue risks.

Alternatively, the contractor may consider decreasing the winter protection period by compressing the activities that fall in that protection period. Two things must then be considered. The first is that if the contractor compresses the activities planned to occur during the winter protection period, will the activities filling the available float also require protection. Overall, this may result in completion of the entire schedule in a shorter time period but not reduce the required shelter time. What would be expected, however, is that the decrease in the overall schedule would result in a decrease in overhead expenses that occur over the entire project duration. The second consideration must be given to whether compression of the schedule will result in additive direct labor and material costs. These compression costs would then only serve to decrease anticipated profit.

CHAPTER IV

CONCLUSION

As can be seen in the previous discussions, there are distinct advantages in working during anticipated adverse conditions. However, there are numerous distinct disadvantages that have not been discussed.

In estimating productivity during periods of adverse climatic conditions, one can only predict the outcome based on occurrences to date. In the previous discussions, it is assumed that a contractor would be able to work continuously through periods of adverse climatic conditions based solely on temperature predictions. Realistically, however, one can expect that the contractor will experience occurrences of work stoppages and delays in delivery of materials during this same time due to not only unusual temperatures but also due to oncoming weather systems (i.e., snow, ice, high winds).

For the example project site, the primary difference between the actual project schedule (Scenario A) and the schedule based on mean temperature data (Scenario C) represents a decrease in profit of \$6,168, or a difference of 1.19% of the actual direct costs. However, even this decrease indicates that it probably will be economically

non-advantageous to conduct construction operations twelve months of the year for this specific project at this specific site.

Other factors must be considered in working during adverse conditions which would also reduce a contractor's anticipated profit. For example, in the case of winter accident costs, it has been clearly shown that the frequency as well as the severity of accidents is substantially higher in the winter, and therefore the additional cost of winter accidents must be considered in the overall cost considerations [8]. Additionally, one must concern themselves with the loss of personnel during periods of adverse weather conditions. On one hand, if the contractor continues work through periods of adverse weather, he or she must also anticipate loss of experienced personnel as a result of accidents or the employees desire to work under better conditions. On the other hand, if the contractor shuts down during long periods of adverse weather, he or she can also anticipate loss of personnel prior to start-up due to the desire to remain employed during that period.

The construction project is essentially an investment for the contractor from which a certain amount of return or profit is generated. Therefore, as a prudent investor, a contractor would tend to limit bids to low risk projects. In the case of adverse weather conditions, the probability for unforeseen conditions is high. Unless the contractor anticipates these unforeseen conditions and plans and docu-

ments accordingly, there is little chance for the contractor to recover from damages [9].

In the case of the example project, only proper planning and documentation during the construction project would result in a successful execution of the project. This prior planning would require estimations of weather conditions similar to what has been done in this report. Then the contractor would be required to document the actual occurrences and note the differences. Without this information, the contractor would have no basis to recover damages.

Without proper planning and documentation, the contractor is only subjecting himself to high risks if pursuing work during periods of adverse weather conditions. If this were determined to be the case with the actual execution of the example project, it is only logical that the contractor would choose to utilize a winter shutdown period.

In conclusion, this report presents one procedure for estimating productivity based on temperature and humidity and traces the impact that these conditions have on scheduling and cost. In addition, this report provides some of the analysis required in making a decision as to whether or not a contractor should work during periods of adverse climatic conditions. While these analyses may be preliminary in nature, it is suggested that they may be sufficient enough to evaluate risks when initially bidding on projects. With this in mind, if the alternative of working

through adverse weather conditions is selected, further refinement of these estimates, together with constant monitoring and adjustment, will be necessary to ensure successful execution of the project and attainment of one's profit objectives.

APPENDIX A

DESCRIPTION OF THE EXAMPLE PROJECT

The Marine Corps Mountain Warfare Training Center (MWTC), Pickel Meadows, is located on a portion of the Toiyabe National Forest in a region defined by the Sierra Nevada Mountains to the west, the Sweetwater Mountains to the northeast, Mono Lake to the southeast, and Lake Tahoe to the north. It is in northwestern Mono County, California, approximately 20 miles northwest of Bridgeport, the county seat, and 17 miles southwest of Walker. Both towns are located on the major north-south access through the region, Interstate 395. Between Walker and Bridgeport, California, Highway 108 intersects with Interstate 395, and the Center is four miles west along the east-west route to the Sonora Pass, one of the few passes through the mountains.

The climate of the region varies considerably with elevation, which ranges from 4,400 feet to 12,512 feet above sea level. The yearly average temperature in the Bridgeport area is 25°F minimum and 61°F maximum, with the lowest temperature recorded approximately -31°F in January and the highest temperature recorded approximately 96°F in August. The Pickel Meadows base camp represents subalpine conditions with an average annual precipitation

of 20 to 40 inches occurring from midwinter through late spring. Snow can remain on the ground from December until May.

The 45,635 acres of land that comprise the Center are rugged and contain steep slopes ranging between 15 to 50 percent. The topography generally slopes from west to east with the highest peaks forming the western boundary of the training area and the lowest elevations along State Highway 108 and the West Walker River. The base camp has a total of 420 acres and has an elevation of 6,760 feet overlooking the West Walker River floodplain.

The Fire Station project was one of a nine-project, \$20 million military construction program started in 1983. This program replaced all "temporary" structures constructed in 1952. Construction of the fire station commenced in September 1984 and was completed in December 1985 [10].

The project itself was to construct a two story building of approximately 4,800 square feet for fire station type use. The facility included an apparatus room, a dormitory, a living/dining area, an alarm/reception area, and administrative areas. Foundations were constructed using spread footings and columns with concrete block foundation walls. Interior and exterior walls were mostly concrete block with gypsum board on metal studs being used in limited areas. Interior supports were steel beams and purlins. The lower level floor consisted of a 6 inch concrete slab reinforced with wire mesh on a 4 inch base. The upper

level floor consisted of a 3-1/4 inch concrete slab reinforced with wire mesh on a 3 inch steel deck. Roofing consisted of a standing seam metal roof on a structural steel deck. Doors consisted of hollow metal and wood in hollow metal frames. Windows consisted of steel frames with tinted insulated glass. Interior finishes consisted of a combination of exposed concrete floors, painted walls, exposed ceilings, vinyl asbestos tile floor coverings, and acoustical tile ceilings. The mechanical system consisted of a forced area heating system and the building was fully fire sprinkled.

As seen in Table A-1 (Page 40), List of Activities, the contractor utilized a total of 69 activities. Table A-2 (Page 41), Example Project CPM Network Based on Contractor's Actual Schedule (Listed by Activity Number, Ascending Order), indicates that the actual contract was performed over a period of 463 calendar days. Of particular note in this network is Activity 4, Winter Shutdown, where the contractor terminated all construction operations (other than caretaker maintenance) for a period of 177 calendar days. Of additional note are the temperatures that could have been expected. As indicated in Appendix E (Page 67), mean minimum monthly temperatures for this period ranged from 8-21 °F. Mean maximum monthly temperatures ranged from 42-66 °F. Mean mean monthly temperatures ranged from 25-43 °F.

	PROJECT DURATION (CD):	466		68	08-Dec-85	08-Dec-85	14-Dec-85	-- C --

Based on the contractor's Schedule of Prices, pricing data obtained from Defense Contract Audit Agency (DCAA) audits, and a base bid of \$721,055, direct costs (labor and material) equalled \$520,406, field overhead costs totaled \$117,384, home office overhead costs totaled \$57,245, and leaving \$26,020 attributable to profit. It is noted that as determined by the DCAA audits, home office overhead was estimated based on an estimated eleven percent of direct costs. Therefore, in the analyses done in this report, it is assumed that direct costs remain constant throughout the comparisons. Only the duration over which the expenditures are incurred change. Therefore, all costs comparisons are performed with no consideration given to home overhead costs only for the purpose of simplifying the comparisons.

APPENDIX B

USE OF LOTUS 1-2-3 FOR CPM NETWORK CALCULATIONS

As indicated previously in Chapter III, the contractor's actual schedule was duplicated on a Lotus 1-2-3 spreadsheet in order that impact on activity duration and slippage of activities could be evaluated instantaneously.

The spreadsheet critical path network utilizes basic formulas found in any network analysis.[11] These basic formulas are as follows:

Early Start = ES = the earliest time that an activity can start

Early Finish = EF = ES + Duration = ES + D

Late Finish = LF = the latest time that an activity can finish

Late Start = LS = LF - D

Float = LS - ES

In addition, basic calculations indicate that when $Float = 0$, then the activity is considered critical.

Information on the spreadsheet used for the CPM network occupied the following ranges of columns and rows:

- 1) Duration for Activities 1-36 - Columns C, Rows 6-41
- 2) Duration for Activities 37-69 - Columns C,
Rows 48-83

- 3) Early Start Dates for Activities 1-36 - Columns G,
Rows 6-41
- 4) Early Start Dates for Activities 37-69 - Columns G,
Rows 48-83
- 5) Late Start Dates for Activities 1-36 - Column H,
Rows 6-41
- 6) Late Start Dates for Activities 37-69 - Column H,
Rows 48-83
- 7) Early Finish Dates for Activities 1-36 - Column I,
Rows 6-41
- 8) Early Finish Dates for Activities 37-69 - Column I,
Rows 48-83
- 9) Late Finish Dates for Activities 1-36 - Column J,
Rows 6-41
- 10) Late Finish Dates for Activities 37-69 - Column J,
Rows 48-83
- 11) Float for Activities 1-36 - Column K, Rows 6-41
- 12) Float for Activities 37-69 - Column K, Rows 48-83
- 13) Critical Activity Flag for Activities 1-36 -
Column L, Rows 6-41
- 14) Critical Activity Flag for Activities 37-69 -
Column L, Rows 48-83

Therefore, combining basic network calculations and the column/row notation used in Lotus 1-2-3, network calculations for the example project as they would be found on the spreadsheet are as follows:

APPENDIX C

DEVELOPMENT OF SCENARIOS C, D, & E

As indicated in Appendix B (Page 44), the contractor's actual schedule was simulated on a Lotus 1-2-3 spreadsheet in order that different scenarios involving activity duration changes could be instantaneously monitored during the process. For the sake of continuity within this Appendix, Table C-1 shows the contractors actual schedule in the Lotus format.

With the basic (actual) schedule in place, it was then decided to develop the ideal case. This case, Scenario B, assumed that all durations indicated on the actual schedule were at an ideal productivity efficiency of 100 per cent. In addition, it was assumed that winter shutdown would be of no consequence in the ideal case resulting in the respective activity duration to be reduced to zero. As indicated in Chapter 3, total project time is reduced to 289 calendar days. The CPM network for Scenario B follows as Table C-2 (Page 57).

With an ideal schedule assumed to be independent of temperature influences, it was then decided to create an expected mean, worst, and best case scenario to identify trends and impact. Scenario C, based on mean climatic conditions, was created by using the calculated productiv-

ity efficiencies indicated in Table 2-3 (Page 14) to modify the ideal case in Scenario B. This resulted in a total project duration of 306 calendar days. The CPM network for Scenario C follows as Table C-3 (Page 59).

As seen in Table C-4 (Page 61), Scenario D, based on temperatures ten (10) degrees below the calculated monthly mean temperatures, total project duration was calculated as 327 calendar days.

Lastly, as seen in Table C-5 (Page 63), Scenario E, based on temperatures ten (10) degrees above the calculated monthly mean temperatures, total project duration was calculated as 296 calendar days.

APPENDIX D

METHOD FOR DERIVING PRODUCTIVITY AS A FUNCTION OF TEMPERATURE AND RELATIVE HUMIDITY

For the purpose of this report, efficiencies in productivity were solely based on the non-linear equations derived by E. Koehn and G. Brown [12]. In deriving these productivity efficiencies, the authors employed historical data for various activities and crafts encompassing a total of 172 data points. From this data, two nonlinear relationships, shown below as Eqs. 1 and 2, were derived relating productivity with temperature and relative humidity - one for cold or cool weather, and another for warm or hot weather. Eq. 1 is applicable from -20°F to 50°F and Eq. 2 from 70°F to 120°F .

where

P_c = productivity factor for cool or cold weather;

P_w = productivity factor for warm or hot weather;

T = temperature in degrees Fahrenheit;

and H = relative humidity as a percent.

In order to represent the productivity as a percent of standard efficient operations, Eqs. 1 and 2 were then normalized as a function of their respective maximum values. Also, to obtain a smooth transition between the two curves, productivity at 60°F and 70°F was arbitrarily taken as unity. Applying the aforementioned expressions, the authors developed Table 2-1 which illustrates the resulting relationships between productivity and temperature for various relative humidities. These relationships are graphically illustrated by way of Figure 2-1 found in the text.

For the example project, each month was individually calculated to derive the productivity efficiency for the specific month and site. Again, calculations were made using a Lotus 1-2-3 spreadsheet.

For each month, values of P_c were calculated for each temperature between absolute minimum temperature and 50°F. These values were then normalized by dividing each efficiency value by the maximum value in the series. The appropriate efficiency value was then selected based on the calculated mean monthly temperature.

Procedures for calculating values of P_w are the same with the exception that values were calculated for each temperature between 70°F and the absolute maximum maximum temperature.

APPENDIX E

CALCULATION OF AVERAGE MONTHLY TEMPERATURES USING THE SIMPLE AVERAGE METHOD

For the purpose of this report, the Simple Average Method was used to estimate average monthly temperatures based on the available data over a twenty year period. Procedures used were as follows:

1) Calculate the mean (using the arithmetic mean) daily mean temperature for each day of the month in question.

2) Assuming a straight line trend, calculate the linear trend occurring for each month. The least squares line for a given series is obtained by using a set of normal equations. These equations are derived mathematically [13] but for working purposes they may be obtained by multiplying the type equation through by the coefficients of each unknown (a and b). In this case, the type equation, which is for a straight line, is

$$Y = a + bX$$

where

a = the Y-intercept

b = slope of the given line

X = X coordinate

Y = corresponding Y coordinate

The coefficient of the first unknown (a) is 1. Therefore, multiplying the type equation through by 1 we have

$$Y = a + bX$$

The formula must be summed up for all points.

The summation results in

$$\Sigma(Y) = \Sigma a + b\Sigma(X)$$

But, the sum of a equals the number of items times the constant

$$\Sigma a = Na$$

Therefore

$$(I) \quad \Sigma(Y) = Na + b \Sigma(X)$$

The coefficient of the second unknown (b) is X.

Multiplying the type equation through by X we obtain

$$XY = aX + bX^2$$

This sums up to

$$(II) \quad \Sigma(XY) = a\Sigma(X) + b\Sigma(X^2)$$

By the use of these two equations the values of the two unknowns can be determined and the trend fitted.

As an example of the above equations, information for the Table E-4 (Page 74) will be used to demonstrate trend calculations. From Table E-4, the following information is obtained:

$$\Sigma X = 406$$

$$\Sigma Y = 814.4$$

$$\Sigma XY = 12013.75$$

$$\Sigma X^2 = 7714$$

Combining with equations I and II above the following is obtained:

$$(I) \quad 814.40 = 29a + 406b$$

$$(II) \quad 12013.75 = 406a + 7714b$$

$$(II) \quad 12013.73 = 406a + 7714b$$

$$(III) \quad \underline{11402.38 = 406a + 5684b} \quad (I \times 14)$$

$$(IV) \quad 611.35 = 2030b \quad (II - III)$$

$$b = 0.30116$$

3) Adjust the mean daily mean temperatures for trend. Each of the averages just computed would then be distorted by the secular trend of the data. If the trend is upward, the adjusted mean daily mean temperature at the end of the month would be higher than it should be in relation to the rest of the days since it occurs later along the trend line.

The increase per month due to trend was determined by fitting a least squares line to the monthly figures and dividing the b value (slope) by the number of days in the month. The resulting value represented the amount each daily average is distorted by the trend as compared to the previous day. This trend adjustment was completed for each month resulting in the listing of average temperatures for the month as seen at the end of this section.

4) With these monthly values established, it was then decided that the temperatures would also require adjustment as the monthly average would also be distorted by the trend

as compared to the previous month. Therefore Steps 1 and 2 were repeated using the monthly values. The results of these calculations follows.

With a line of regression used to estimate a theoretical value of Y for a given value of X, if the relationship is not perfect the actual values will not usually coincide with the theoretical values because of scatter. If the scatter is definitely measured the variation may then be allowed for. For this purpose the standard error of estimate was used to measure the variation or scatter about the line of regression. This standard error of estimate is used similarly to the standard deviation.

Tables E-1 through E-37 utilize the above noted procedures and provide data for the months of January through December. This data provides the basis for the productivity efficiency estimates listed in Table 2-3 (Page 14).

APPENDIX F

CALCULATION OF HEATING REQUIREMENTS AND COSTS FOR TEMPORARY ENCLOSURE FOR SCENARIOS C, D, & E

Calculations for the heating requirements for the temporary enclosure were base on the relationship derived by F. Lawrence Bennet [14] where

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (dT)$$

in which dT = difference between inside and outside temperature, in degrees Farenheit.

Daily costs for fuel were then calculated where

$$\begin{aligned} \text{DAILY FUEL COST} &= \text{BTU's/CU FT/DAY} \times \text{CU FT OF ENCLOSURE} \\ &\quad \times \text{FUEL COST PER 100,000 BTU} \end{aligned}$$

For the purpose of this report, it was assumed that the desired interior temperature of the enclosure was 50°F and that fuel oil for the heaters cost \$0.32/100,000 BTU. As noted in Chapter III, the selected enclosure contains 348,348 cubic feet of space.

Fuel calculations for Scenario C (using calculated mean temperatures) are as follows:

NOVEMBER:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-34) = 96.64$$

$$\begin{aligned} \text{Daily Cost} &= 96.64 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$107.73/\text{DAY} \end{aligned}$$

DECEMBER:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-26) = 101.15$$

$$\begin{aligned} \text{Daily Cost} &= 101.15 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$112.75/\text{DAY} \end{aligned}$$

JANUARY:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-25) = 101.71$$

$$\begin{aligned} \text{Daily Cost} &= 101.71 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$113.38/\text{DAY} \end{aligned}$$

FEBRUARY:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-28) = 100.02$$

$$\begin{aligned} \text{Daily Cost} &= 100.02 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$111.49/\text{DAY} \end{aligned}$$

MARCH:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-33) = 97.21$$

$$\begin{aligned} \text{Daily Cost} &= 97.21 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$108.36/\text{DAY} \end{aligned}$$

Fuel calculations for Scenario D (using calculated mean temperatures plus ten degrees) are as follows:

NOVEMBER:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-44) = 91.02$$

$$\begin{aligned} \text{Daily Cost} &= 91.02 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$101.46/\text{DAY} \end{aligned}$$

DECEMBER:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-36) = 95.52$$

$$\begin{aligned}\text{Daily Cost} &= 95.52 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$106.48/\text{DAY}\end{aligned}$$

JANUARY:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-35) = 96.08$$

$$\begin{aligned}\text{Daily Cost} &= 96.08 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$107.10/\text{DAY}\end{aligned}$$

FEBRUARY:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-38) = 94.39$$

$$\begin{aligned}\text{Daily Cost} &= 94.39 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$105.22/\text{DAY}\end{aligned}$$

MARCH:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-43) = 91.58$$

$$\begin{aligned}\text{Daily Cost} &= 91.58 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$102.09/\text{DAY}\end{aligned}$$

APRIL:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-48) = 88.77$$

$$\begin{aligned}\text{Daily Cost} &= 88.77 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$98.95/\text{DAY}\end{aligned}$$

Fuel calculations for Scenario E (using calculated mean temperatures minus ten degrees) are as follows:

NOVEMBER:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-24) = 102.27$$

$$\begin{aligned}\text{Daily Cost} &= 102.27 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$114.00/\text{DAY}\end{aligned}$$

DECEMBER:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-16) = 106.78$$

$$\begin{aligned} \text{Daily Cost} &= 106.78 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$119.02/\text{DAY} \end{aligned}$$

JANUARY:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-15) = 107.34$$

$$\begin{aligned} \text{Daily Cost} &= 107.34 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$119.65/\text{DAY} \end{aligned}$$

FEBRUARY:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-18) = 105.65$$

$$\begin{aligned} \text{Daily Cost} &= 105.65 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$117.77/\text{DAY} \end{aligned}$$

MARCH:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-23) = 102.84$$

$$\begin{aligned} \text{Daily Cost} &= 102.84 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$114.63/\text{DAY} \end{aligned}$$

APRIL:

$$\text{BTU's/CU FT/DAY} = 87.64 + 0.5628 (50-28) = 100.02$$

$$\begin{aligned} \text{Daily Cost} &= 100.02 \frac{\text{BTU/CF}}{\text{DAY}} \times 348,348 \text{ CF} \times \frac{\$0.32}{100,000 \text{ BTU}} \\ &= \$111.50/\text{DAY} \end{aligned}$$

For the rental of the heaters, it was assumed that three (3) 500 MBH oil fired heaters would be required. At an estimated cost of \$480 per month per heater, daily cost for the three heaters was calculated at \$47.34 per day.
